healing or functional outcomes

metacarpal fractures occurring in 2nd through 5th digits

be initiated in the first 21 days after fracture or reduction.

Outcome Measures
Standardized hand function or health-related quality of life, functional strength, mobility, pain, satisfaction, activities of daily living, instrumental activities of daily living.

Field et al. (2000)

To evaluate the effects of massage therapy on reduction of postburn itching and pain and on reduction of anxiety and depressed mood

Level I

RCT

Participants

N = 20 participants (mean age = 38.2 yr) randomly assigned to massage therapy (treatment group) or standard care (control group)

Intervention

Control group received standard medical care (physician visits, medication, physical therapy or occupational therapy, cocoa butter to closed wounds without massage).

Treatment group received massage therapy for 30 min, 2 times/wk for 5 wk.

Massage therapists applied mild to moderate pressure with cocoa butter as a lubricant in a stroking manner; pressured movements from perimeter of wound to center using pads of fingers; circular, transverse, and vertical strokes for 10 min; skin rolling; and long strokes.

Outcome Measures

Participants rated their itching severity, pain, anxiety and depressed moods using a visual analog scale, McGill Pain Questionnaire, STAI, and the Profile of Mood States.

Treatment group experienced reduced itching, anxiety, depressed mood, and pain. Long-term improvement occurred in all areas from before 1st treatment day to last treatment day.

• No study reported use of a standardized measure of time to clinical or bony union or a score on a standardized hand function test or quality-of-life test instrument.

• Participants were all from a low socioeconomic status group; unclear whether results are generalizable.

• Standard medical care that was continued by physical or occupational therapist is not fully described.

• Unclear whether this standard treatment included methods that may have contributed to outcomes.

Guzelkucuk et al. (2007)

To compare the efficacy of therapeutic activities that simulate ADLs with that of traditionally used therapeutic exercises in the management of injured hands in young adult patients

Level I

RCT

Participants

N = 36 participants with functional hand loss resulting from injury; 20 allocated to

Intervention

Control group was provided with an appropriate twice-daily treatment program including passive, active assisted, and AROM and strengthening activities.

Although both groups improved at 2-mo follow-up, there were statistically significant differences (including functional outcomes) between the groups in favor of the

• Study was not blind, compliance with home program was not assessed, chronic and acute conditions were included in both groups, and efficacy of activities with specific

</tr>
</tbody>
</table>
Participants

N = 24 trials

for CTS, including splinting, ultrasound, nerve-gliding exercises, yoga, LLLT, magnetic therapy, manual therapy, acupuncture, and combined therapies. Studies explored effects of these therapies on areas such as general symptomatology, severity of pain, sleep, nerve conduction studies, numbness and tingling, morning stiffness, paresthesias, tactile sensation, and pinch-and-grip strength.

Effective. Twenty 15-min treatments of deep, pulsed ultrasound decreased symptoms, reduced sensory loss, and improved median nerve conduction and strength. 10 treatments of superficial, continuous ultrasound for 5 min were not effective.

Nerve-gliding exercises reduced pain and increased ROM compared with no treatment. 1 session of brief magnetic therapy did not decrease pain more than sham treatment; both decreased pain. Prolonged therapy in wrist support wraps improved symptoms of numbness and tingling and improved nerve conduction studies more than sham treatment. Laser therapy was supported by 1 study.

Biweekly Hatha yoga sessions improved symptoms but not grip strength or pain more than splinting alone did. Manual therapy effectively relieved pain, but stretches of Digits 3 and 4 did not change nerve conduction in CTS.

Nash, Mickan, Del Mar, & Glasziou (2004)

To determine whether benefit or harm comes from mobilizing or immobilizing an acute limb injury in adults

Systematic review

Participants

N = 3,366 participants

49 trials of immobilization for soft tissue injuries and fractures of both upper and lower limbs were identified. 2 reviewers selected articles.

Studies were divided into 4 groups: lower-limb fractures, other lower-limb injury, upper-limb fractures and other upper-limb injuries. Groups were further divided into trials using limb support vs. no support.

Outcome Measures

- Patient-centered outcomes
- Measures of global function, including subjective and objective criteria: pain, stiffness, swelling; use of magnets in place; splints alone have been found to be effective.

Manual therapy results depended on particular techniques being used.

• Reviewers did not contact authors for clarification or updated research. Many studies were of poor quality; review focused on studies of higher quality only.
• Reviewers did not list all diagnoses included in all studies; it is not known whether acute tendon repairs, nerve injuries, or joint replacements (as examples) were considered

<td>Several studies had high levels of bias.</td>
</tr>
</tbody>
</table>

**Author/Year**: O'Brien & Pandit (2006), O'Connor et al. (2003)

**Study Objectives**:
- To determine the effect of silicone gel sheeting for prevention or correction of hypertrophic or keloid scarring in people with newly healed wounds and people with established scars.
- To evaluate the effectiveness of nonsurgical treatment (other than steroid injection) for CTS vs. a placebo or other nonsurgical, control interventions in improving clinical outcomes.

**Level/Design/Participants**:
- O'Brien & Pandit (2006): Level I Cochrane Systematic Review. Participants: 13 trials with 559 participants ages 2–81 yr were included in review.

**Intervention and Outcome Measures**:
- Supports, stair climbing, work, sport play and ADLs
- ROM
- Deformity and other complications
- Patient preference

**Results**:
- Prevention trials, when compared with no treatment, indicated reduced incidence of hypertrophic scarring.
- Gel sheeting increased scar elasticity in established scar.

**Study Limitations**:
- As part of early mobilization group.
- Both prevention and correction studies were highly susceptible to bias and considered poor-quality studies by reviewers. Reviewers suggest caution when using the results of these studies.

<td>Richard et al. (1987)</td>
<td>To investigate 2 common interventions for increasing finger-flexion ROM, passive exercise, and static wrapping</td>
<td>Level I RCT; counterbalanced repeated</td>
<td>Intervention&lt;br&gt;Passive ROM exercise was administered to involved finger joints (except distal interphalangeal joint) by the therapist for 10 min.&lt;br&gt;Affected joints were wrapped in full mitten configuration by therapist using 3-in. elastic bandage; wrap was left in place for 10 min.&lt;br&gt;13 trials of each technique. brake were conducted. Timeframe was not reported.</td>
<td>evidence that vitamin B6 is not effective and that full-time use of splints is effective. Limited or conflicting evidence that NSAIDS, diuretics, yoga, laser, and ultrasound are effective, and evidence that exercise and botulinum toxin B are ineffective.</td>
<td>• Review may have overlooked studies that could have added important insight to conclusions.</td>
</tr>
<tr>
<td>Rogers &amp; Wilder (2007)</td>
<td>To determine the effects of 2 yr of whole-body strength training and gripper exercise on hand strength, pain, and function in adults with radiographic evidence of hand OA</td>
<td>Level III Pre- and posttest design with single group</td>
<td>Intervention&lt;br&gt;Participants completed a structured strength-training routine that addressed muscular strength, endurance, and joint mobility. The 25- to 30-min routine included warm-up, strength training, and cool down.</td>
<td>Older adults with radiographic evidence of hand OA and minimal dysfunction demonstrated increase in static and dynamic grip strength by completing whole-body strength training that includes gripper exercise. Those adults with symptomatic OA were able to reduce pain while increasing strength.</td>
<td>• Unclear when pain assessment was completed. • Isotonic hand gripper cannot be evaluated independent of whole-body strength-training routine. • Assessment and training did not include pinch strength.</td>
</tr>
</tbody>
</table>
| Rogers & Wilder (2009) | To investigate the effects of a daily 16-wk home exercise regimen on hands with OA | Level I RCT  
**Intervention**  
Both investigational protocol and sham protocol were included. The procedure was 16 wk of activity and a wash-out period of 16 wk with no intervention. Following wash-out period, the groups were switched.  
Investigational group was given 9 hand exercises that involved ROM and strengthening.  
Placebo group was instructed in a hand massage program using a nonvigorous and gentle technique.  
**Outcome Measures**  
Australian Canadian Osteoarthritis Hand Index physical function subscale (includes self-reports), Jamar grip and pinch dynamometers, and Perdue pegboard  
Home-based daily exercise program modestly increased grip-and-pinch strength, but this benefit was not enough to be seen in self-reported hand function or pain. No change noted in Perdue pegboard test.  
- Daily progressive protocol may have been too aggressive for older population.  
- Investigator was not blind to treatment vs. sham group. |
| Severens et al. (1999) | To study the cost-effectiveness of adjunctive treatment of patients with RSD of 1 extremity | Level I RCTs  
**Intervention**  
Treatments were provided to patients per preestablished protocols.  
Participants kept diaries for 2 wk of visits to therapy and other venues needed as a result of RSD and of money spent on medications and related supplies. They also showed a difference between physical therapy vs. occupational therapy and computed tomography. Physical therapy and occupational therapy were more costly than computed tomography, but none showed higher medical costs.  
- Functional abilities and disability were not measured.  
- Monetary values and cost of medical care in the Netherlands may not be generalizable to the United States.  
- Protocols used or frequencies and durations of treatments were not provided.  |

Regimens for patients with trapeziometacarpal OA

Participants

N = 40; participants complained of pain at the base of the thumb and had been diagnosed with Stages I–III trapeziometacarpal OA.

Routine and a thumb splint known as the thumb strap splint, designed to prevent flexion and adduction of the metacarpal, dorsoradial subluxation of the base of the first metacarpal and metacarpophalangeal hyperextension.

The control group was instructed to wear a short opponens splint.

Both groups were instructed to wear the splints full time for a period of 2 wk. For Wk 2–6, splinting continued with the addition of the exercise regiment.

For the experimental group, the exercises consisted of pain-free abduction exercise only; the control group received a typical treatment program that included pain-free pinching exercises with a soft foam block.

Outcome Measures

Pain, strength, and hand function.

Differences in pain, strength, or hand function noted after 4-wk exercise and splint program (Wk 2–6). Overall, both groups did improve statistically in all 3 areas.

Improvements such as the Hawthorne effect, the placebo effect, and the method of statistical regression.

Weinstock-Zlotnick et al. (2004)

To compare the effects of PGWGs with sueded palm and SPGGs on functional hand use in people with hand burns.

Level III

Quasi-experimental, nonrandomized, repeated-measures design

PGWG served as the experimental condition, and SPGG served as control condition; each participating hand was its own control.

Participants

2 individuals (a total of 3 burned hands) participated in the study.

Intervention

Participants were given 2 types of pressure garments: 1 SPGG and 1 PGWG. Each was worn for 1 wk to acclimate the participant to fit and use. Testing was completed at the participant’s home at the same time of day in the same living area. Participants selected the glove they preferred to wear; testing was separated by a period of 1 or 2 wk to decrease likelihood of training effect.

In general, the 3 participating hands scored better in the PGWG condition than in the SPGG condition in functional hand tasks. The work glove was unanimously preferred and described as the ideal choice if only 1 glove was to be allocated. Changes in functional hand use were significant.

- Small sample size; convenience sample may not be appropriately generalized to larger populations.
- Likert scale used for rating ADL abilities relied on memory of task difficulty, not on actual task performance. Likert scale may not have been a sensitive instrument.

| Werner et al. (2005) | To determine whether night splinting of workers identified with CTS would improve symptoms and median nerve function and affect medical care | Level I RCT Participants N = 112 auto workers reporting symptoms of CTS | Intervention Both groups (treatment n = 63; control n = 49) were given instructions in how to reduce ergonomic stressors in both work and home environments via a 20-min video. Treatment group was fitted with a custom hand–wrist orthosis that placed the wrist in neutral. The most symptomatic hand was chosen for study in those participants with bilateral hand involvement. Splints were to be worn at night for 6 wk.                                                                                                                                 | 6-wk trial of splinting reduced discomfort scores; no difference was reported in the symptom severity scale scores; improvements persisted for 12 mo. Both groups improved over time, but improvements were greater in the treatment group. No difference in nerve conduction studies was shown between the 2 groups between pre- and poststudy measurements. | • Participants were not blinded to their treatment, and the primary outcome measure was a self-reported questionnaire.  
• Participants were not fully evaluated at 3- and 6-mo intervals.  
• Statistical methodology and loss of participants may have confounded the analysis in the logistic model.  
• Symptoms in the control group were found to be more severe than those in the treatment group, despite randomization. |
| Wessel (2004)    | To evaluate the efficacy of hand exercises for people with rheumatoid arthritis | Level I Systematic review of comparative trials and case studies | Intervention Interventions included any form of hand exercise such as ROM, strengthening, endurance exercises, or motor control | Value of hand exercise in the treatment of RA is not conclusive, although weak evidence exists that appropriate exercises might lead to long-term strength | • Lower quality studies were used in review.  
• Studies used did not mention expected change that would be considered clinically important. |
Participants

*N* = 402 (9 trials)

or relearning. Interventions could include a combination of exercise and modalities.

Outcome Measures

Included strength, ROM, dexterity, pain, stiffness, and self-report of function as related to impairments or outcomes of the hand changes and very short-term changes in stiffness. In general, meta-analysis was not possible because of the wide range of study designs and outcome measures.

Studies lacked power calculations.

Little attempt was made to blind studies or introduce placebo to participants.

Studies did not highlight a specific form of intervention.

Williams et al. (2004)

To evaluate the available evidence on workplace rehabilitation interventions for work-related upper-extremity disorders

Level I

Systematic review

Participants

*N* = 751 (8 trials) for those receiving workplace-based interventions for upper-extremity disorders

Intervention

Workplace interventions included ergonomic modifications to the workplace to decrease repetitiveness, force, and awkward positioning; job accommodations included modified work, light-duty work trials, and graded return to work.

Outcome Measures

Evidence is insufficient to identify effective workplace rehabilitation interventions for work-related upper-extremity disorders. Although several studies reported positive findings, some studies identified for inclusion in review and flaws in the studies limited the ability of this review to make generalized recommendations.

Studies were limited by small sample size, lack of standardized outcome measures, and inadequate reporting of interventions and results.
